

# Using water vapor isotopic measurements to evaluate moist and cloud processes in general circulation models

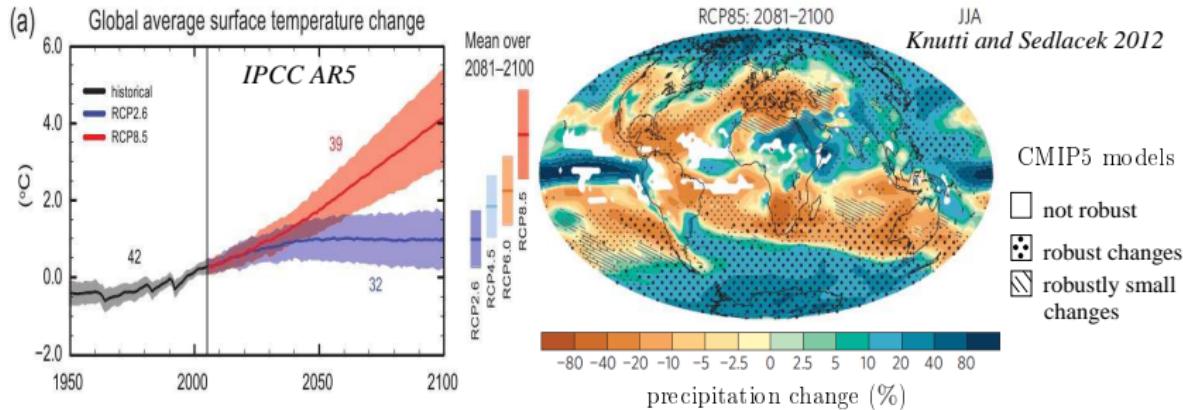

Camille Risi

LMD/IPSL/CNRS

with the contribution of: Sandrine Bony, Valérie Masson-Delmotte, You He,  
Jean-Lionel Lacour, Boutheina Oueslati, Obbe Tuinenburg, Françoise Vimeux,  
John Worden

NASA-JPL, October 16, 2014

# Moist and cloud processes in climate models

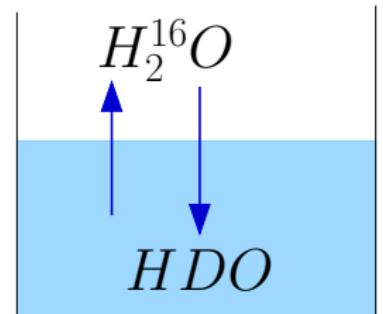

- ▶ Sources of spread? Temperature: cloud feedbacks (*Bony et al 2004, Dufresne et al 2008, Vial et al 2014*)
- ▶ For precip: convective parameterizations, cloud feedbacks?  
(e.g. *Kang et al 2008, Frierson and Hwang 2012*)

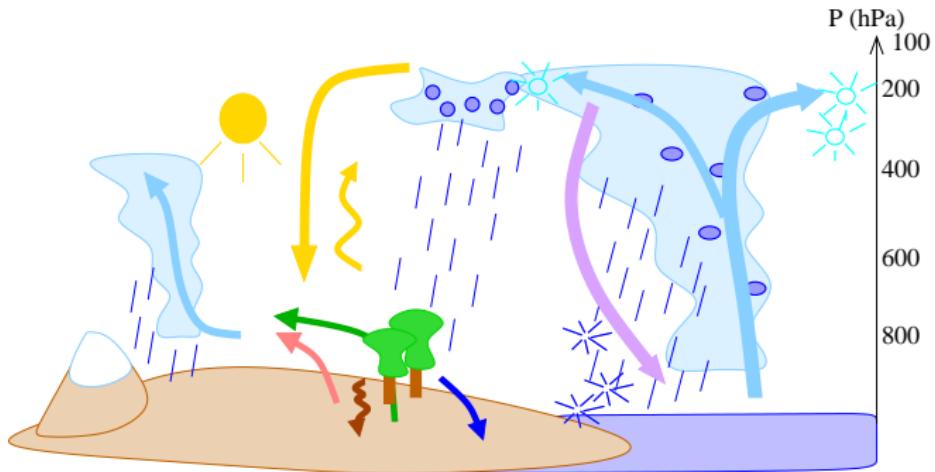

⇒ Need to better evaluate these processes in models

# Water isotopes

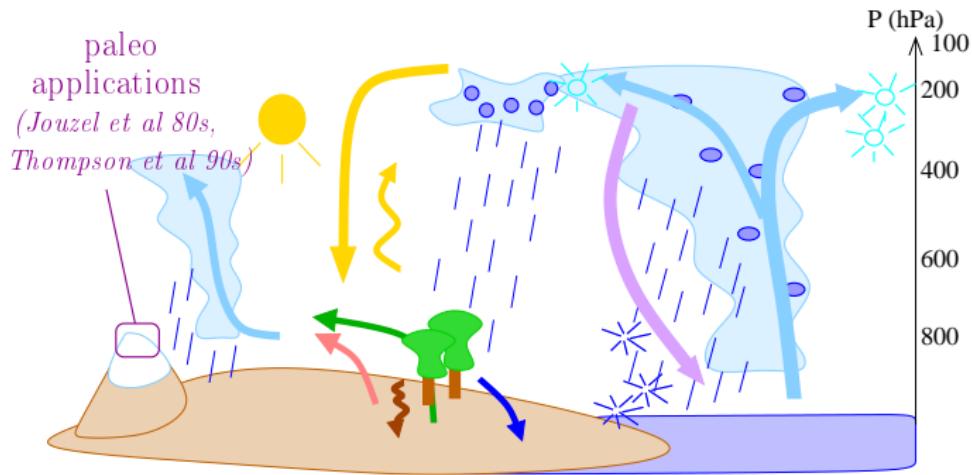

- ▶  $H_2^{16}O$ ,  $HDO$ ,  $H_2^{18}O$  ...
- ▶  $\delta D = (HDO/H_2O/R_{sea\ water} - 1) \cdot 1000$  in ‰
- ▶ fractionation during phase changes  
⇒ tracers of the water cycle

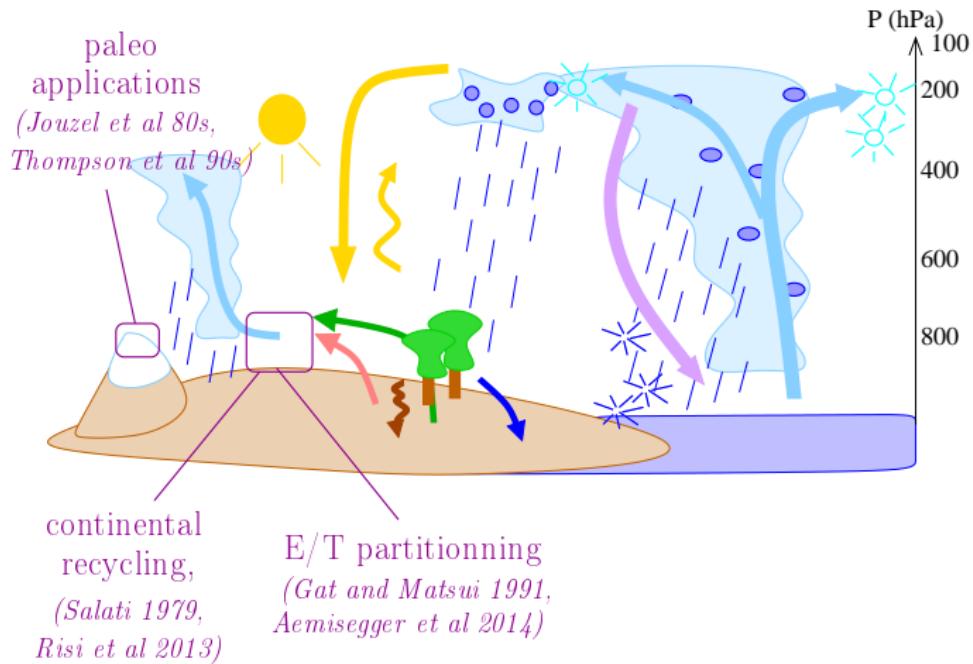

# What can we use isotopes for?

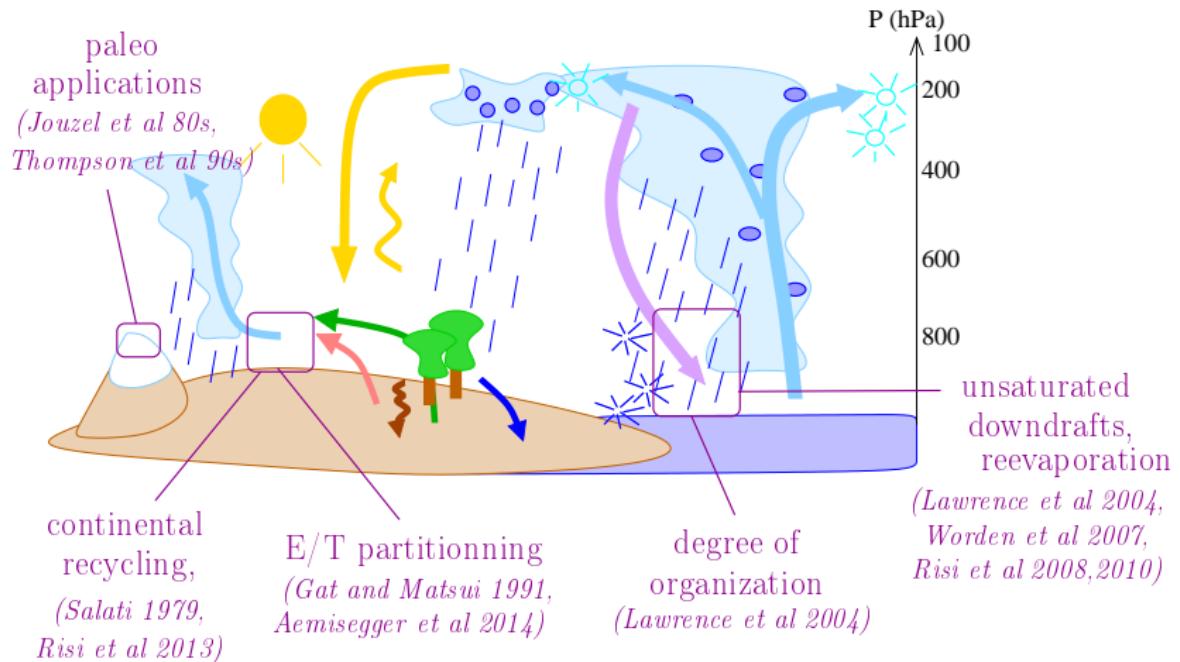

# What can we use isotopes for?

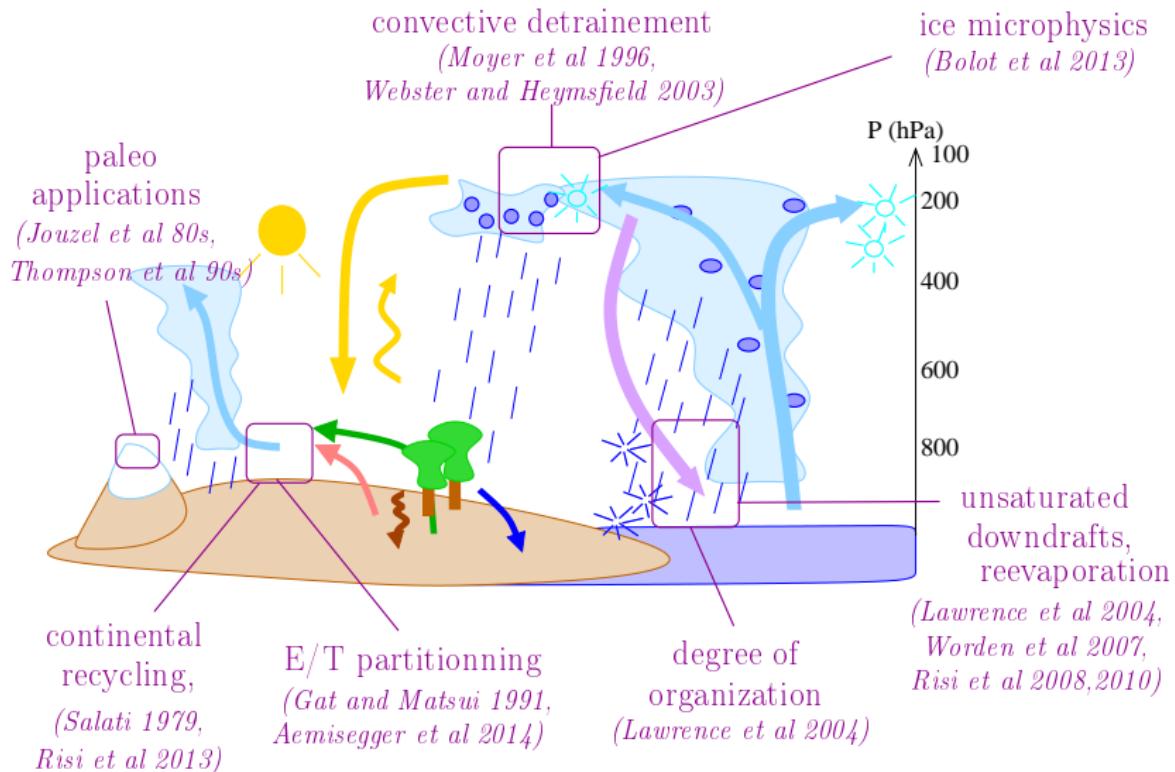

# What can we use isotopes for?

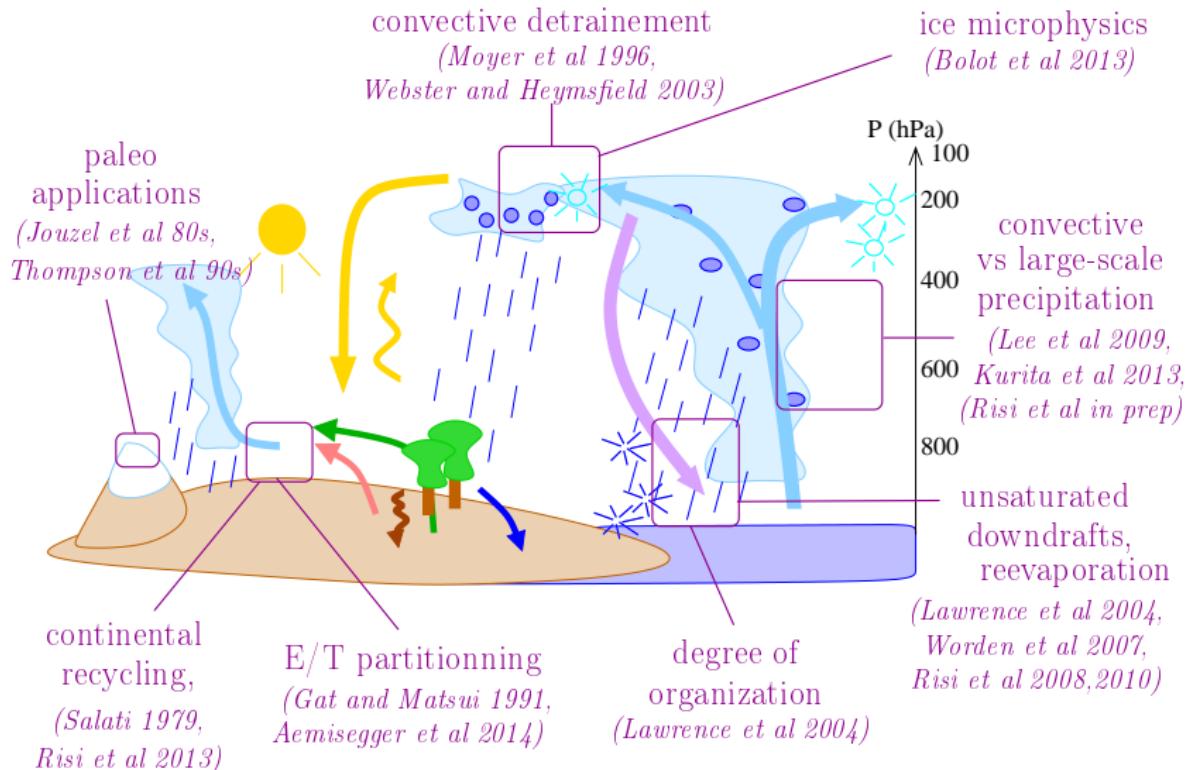

# What can we use isotopes for?

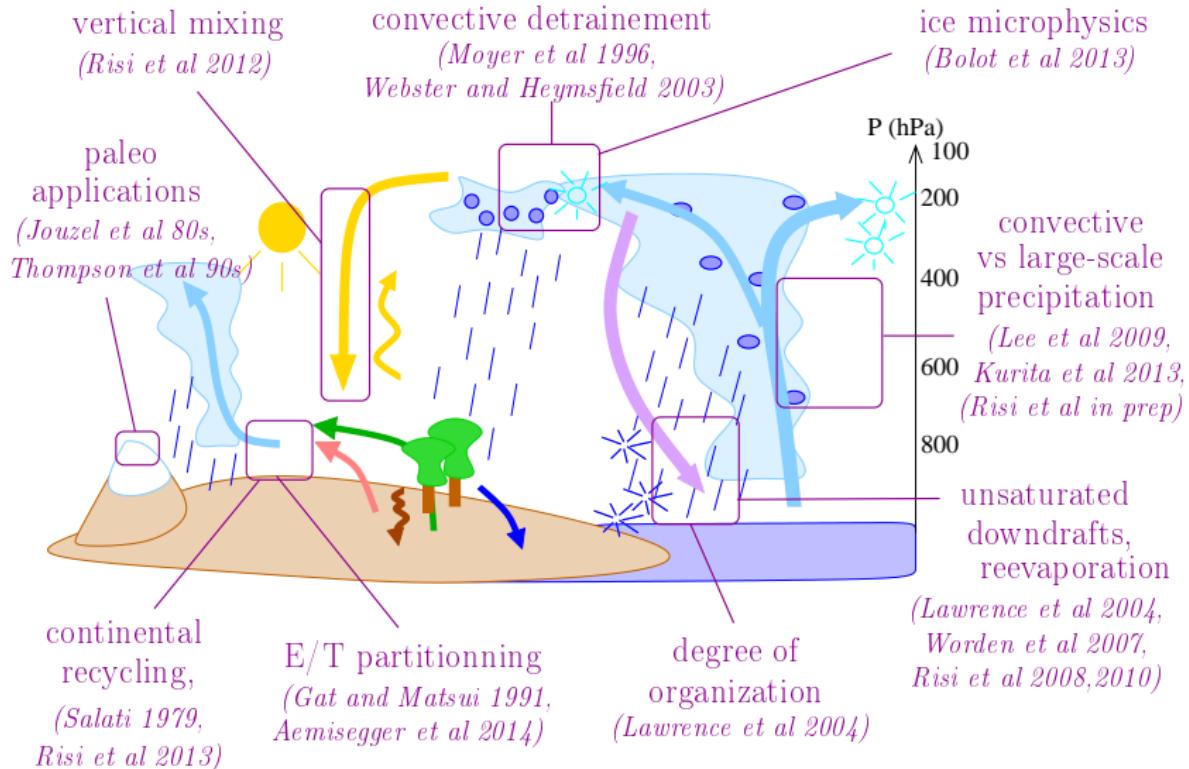

# What can we use isotopes for?

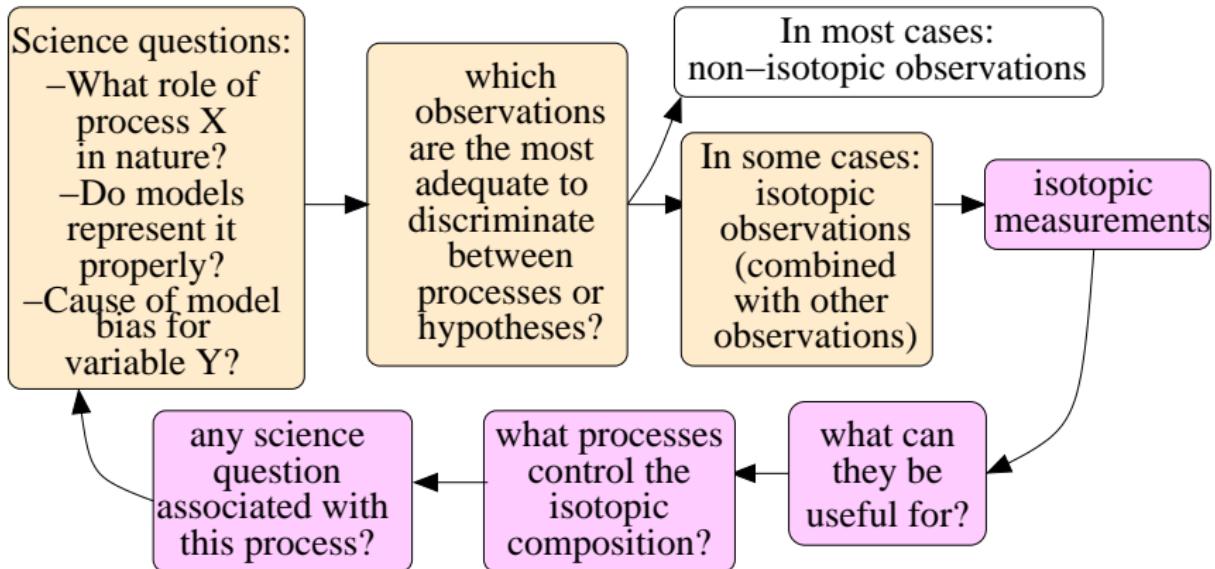

# What can we use isotopes for?

# What can we use isotopes for?

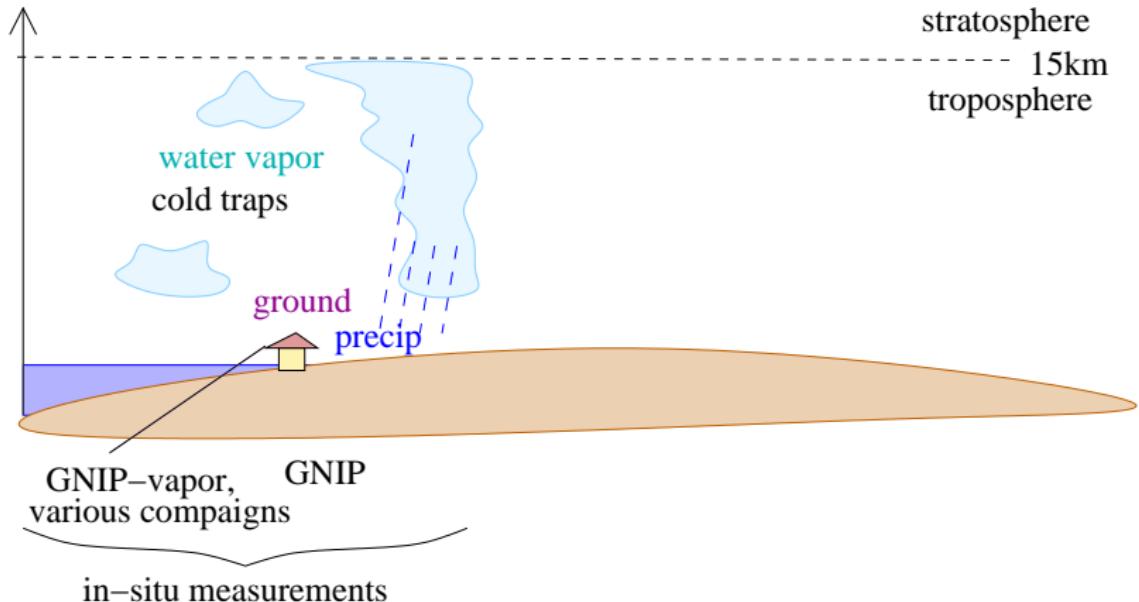

# Why do we want isotopes to be useful?

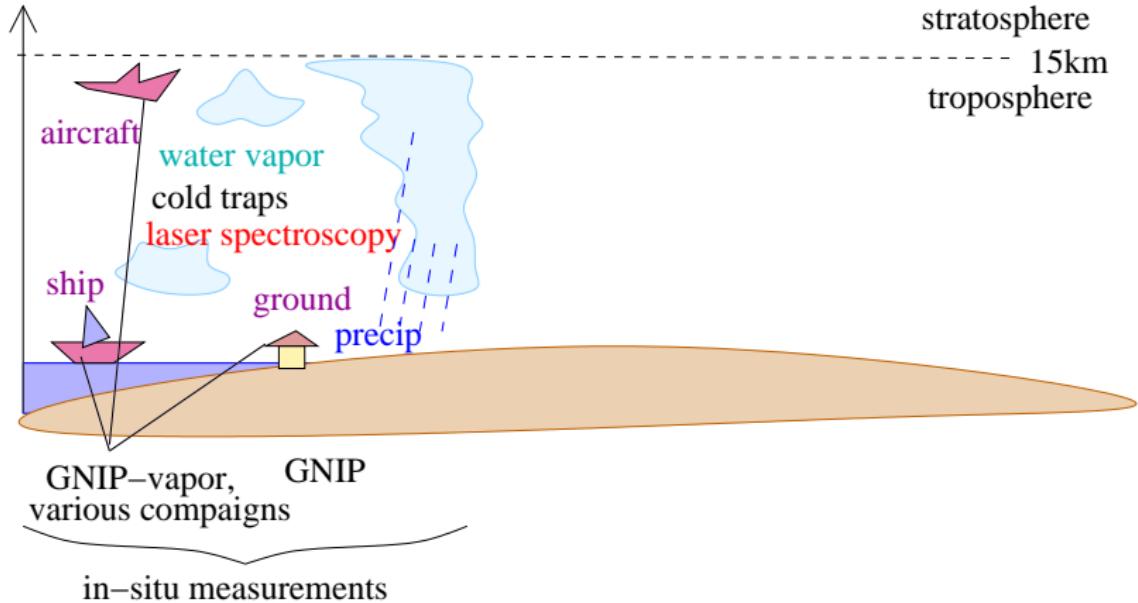

# Seminar outline and summary

1. recent developments in water vapor isotopic measurements and models
2. Upper troposphere:  $\delta D$  sensitive to moistening by convective detrainment
3. Mid-troposphere: what does the  $\delta D$ -precipitation link says about the model physics?
  - 3.1  $\delta D$  reflects shallow vs deep convective mixing and associated large-scale circulation
  - 3.2  $\delta D$  reflects convective vs large-scale precipitation and associated heating profiles
4. During MJO events: mid-tropospheric  $\delta D$  evolution reflects the relative timing of different cloud types and associated moistening and dehydrating processes

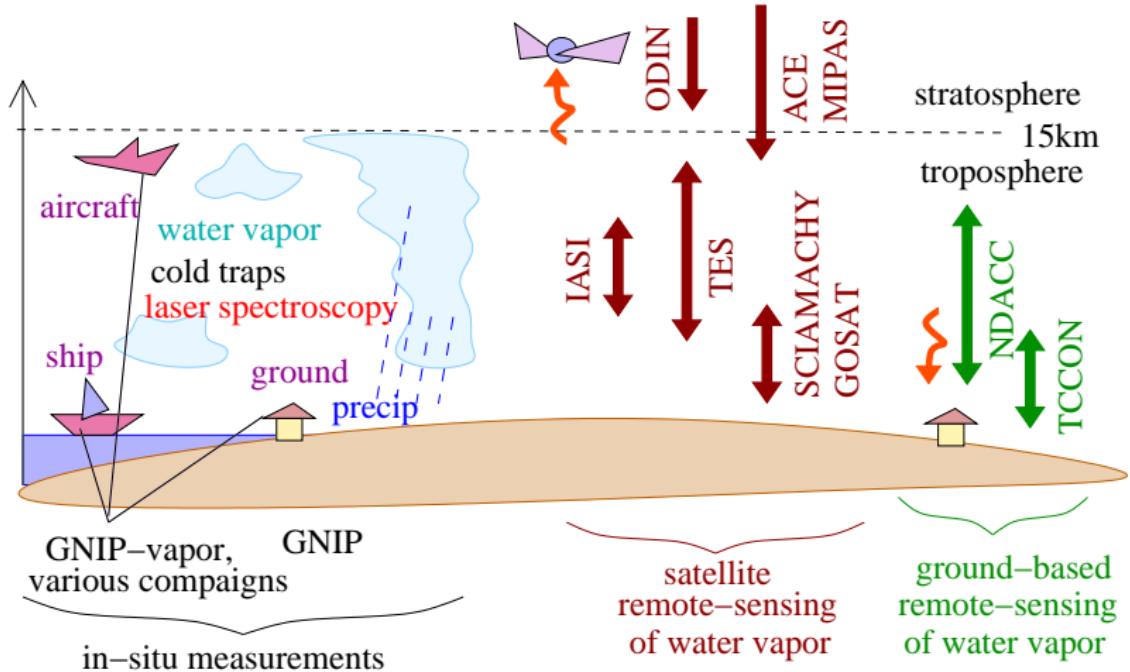

# Measurements

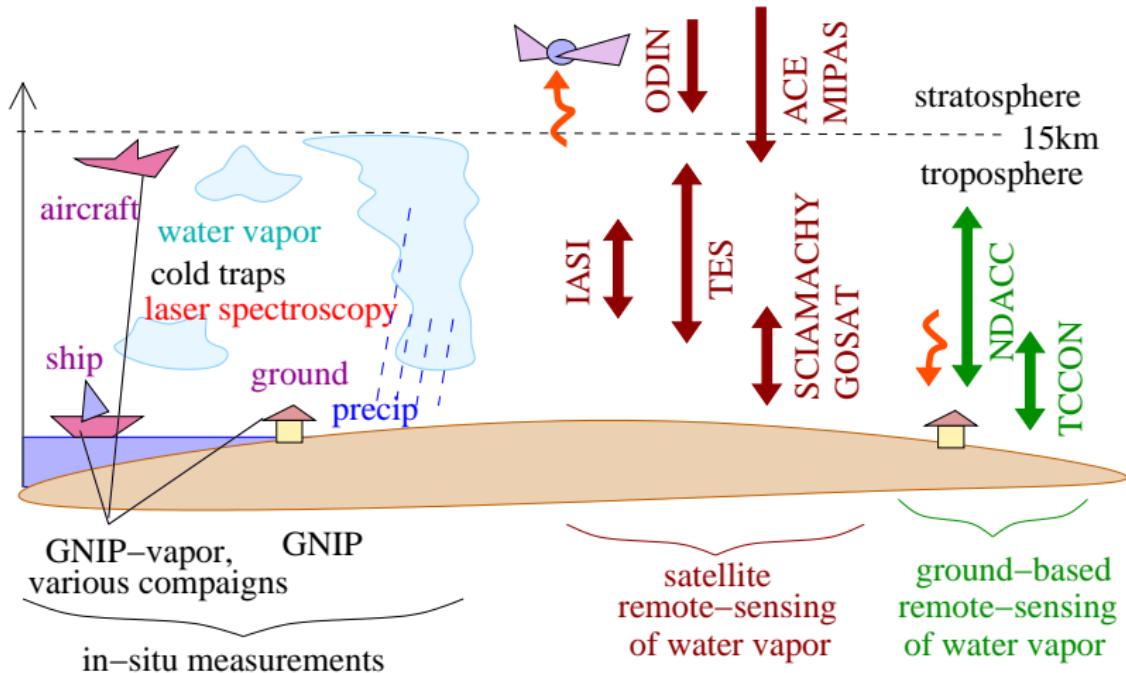

# Measurements

# Measurements

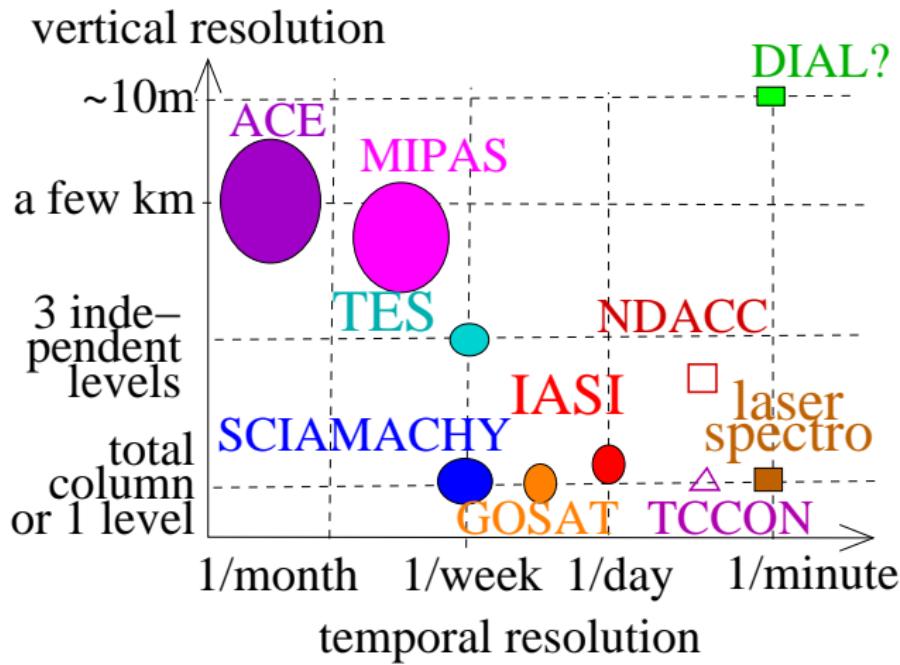

# Measurements

- ▶ TES: weekly vertical profiles of  $\delta D$
- ▶ IASI: 2 daily global coverage of  $\delta D$

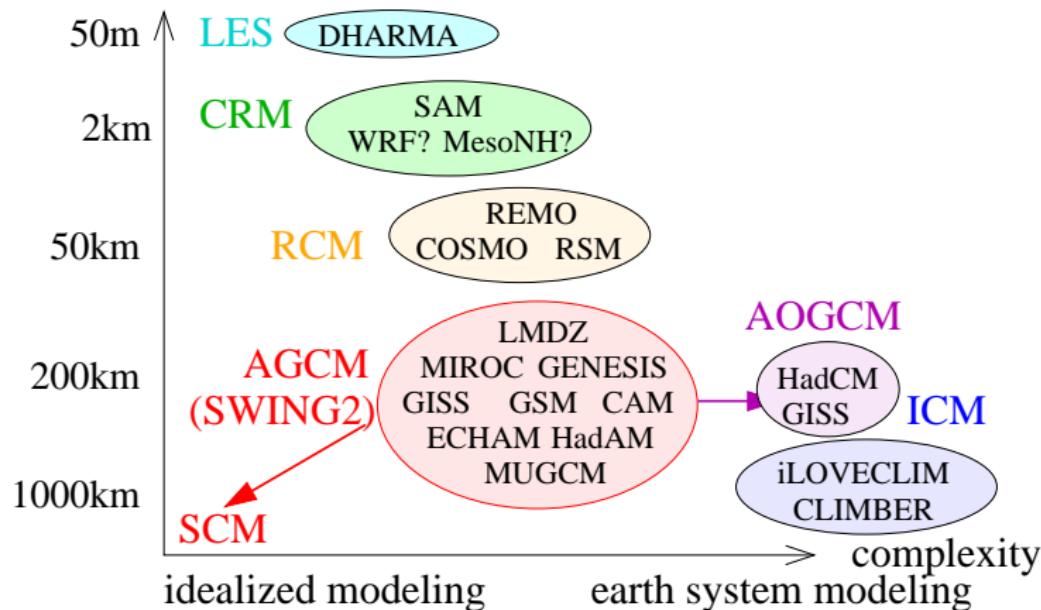

# Diversity of measurements

- ▶ different altitudes, temporal resolution, vertical resolution, precision, spatial resolution and coverage...

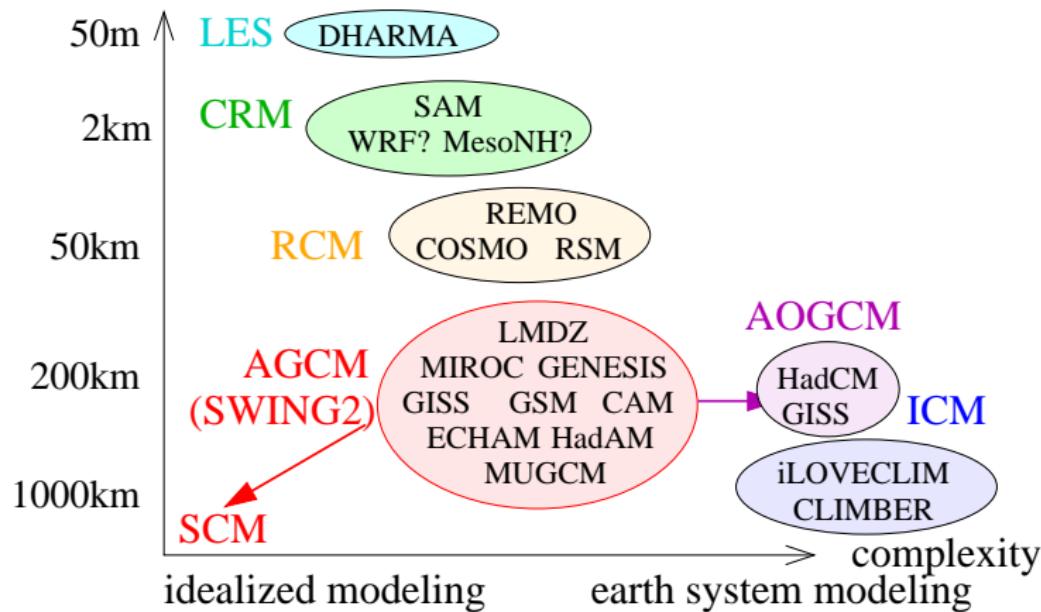

# Numerical models

spatial resolution

# Numerical models

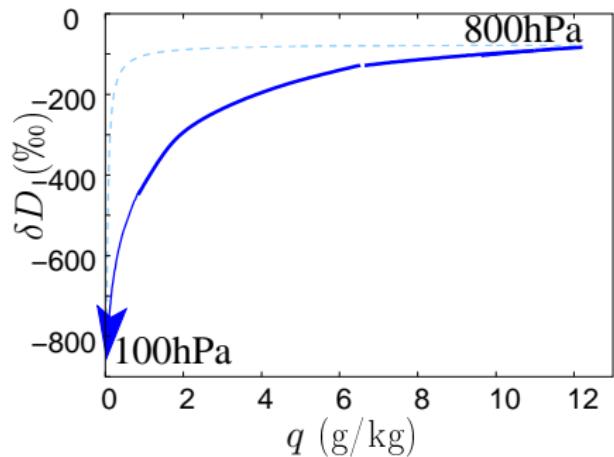

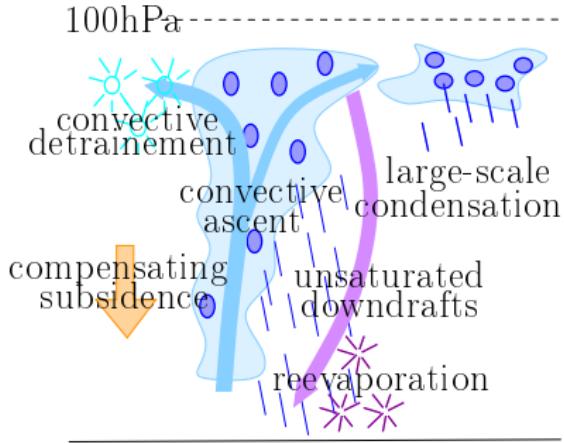

spatial resolution

- Here: LMDZ model, SWING2

# Theoretical framework: $q-\delta D$

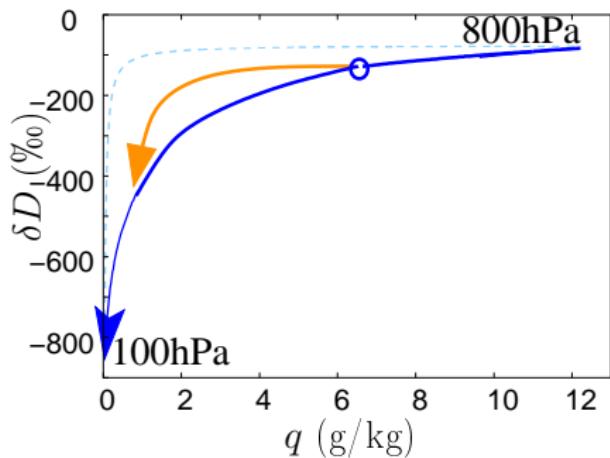

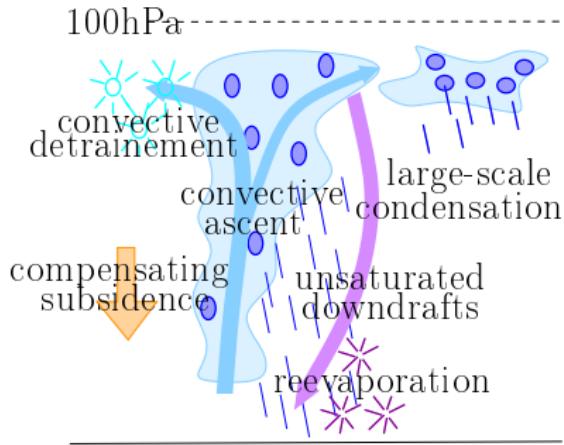

- ▶ Moistening and dehydrating processes (*Worden et al 2007*)

→ large-scale condensation

# Theoretical framework: $q-\delta D$

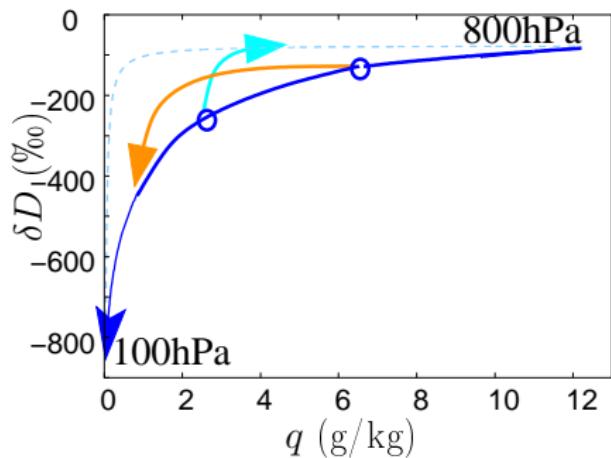

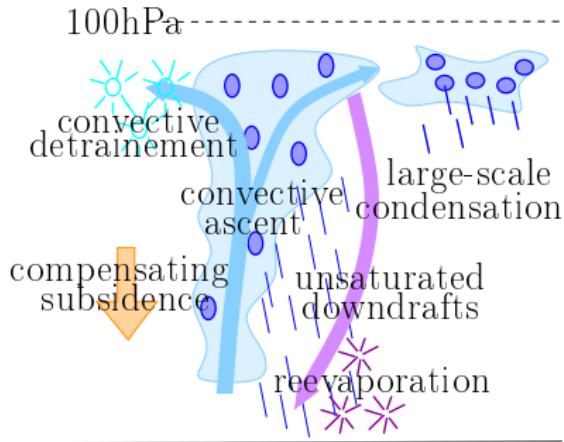

- ▶ Moistening and dehydrating processes (*Worden et al 2007*)

- ▶ large-scale condensation
- ▶ subsidence

# Theoretical framework: $q-\delta D$

- ▶ Moistening and dehydrating processes (*Worden et al 2007*)

large-scale condensation

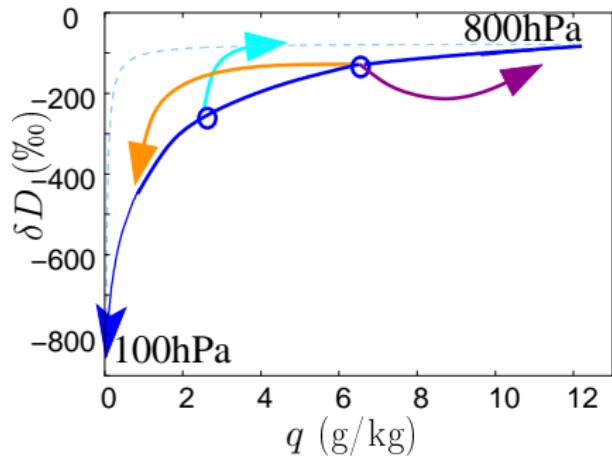

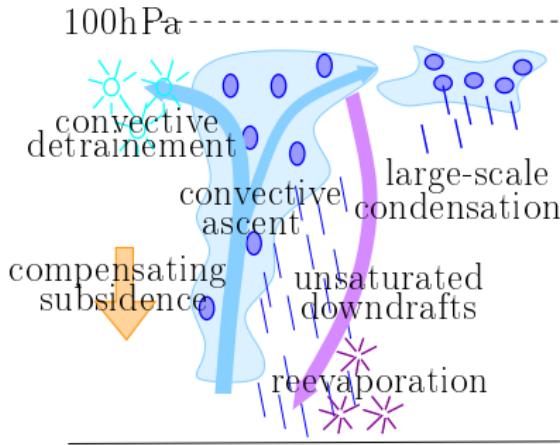

subsidence

detrainment

# Theoretical framework: $q-\delta D$

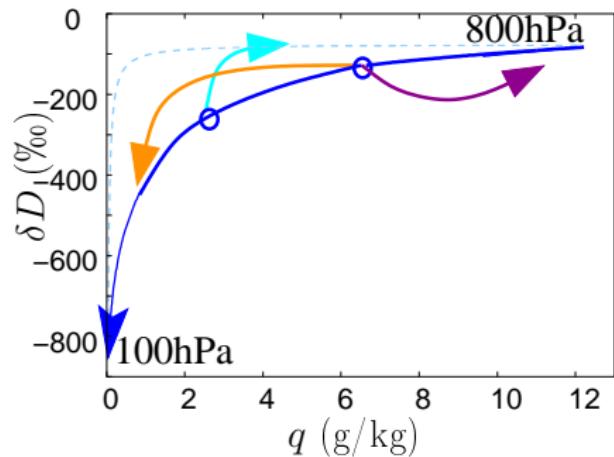

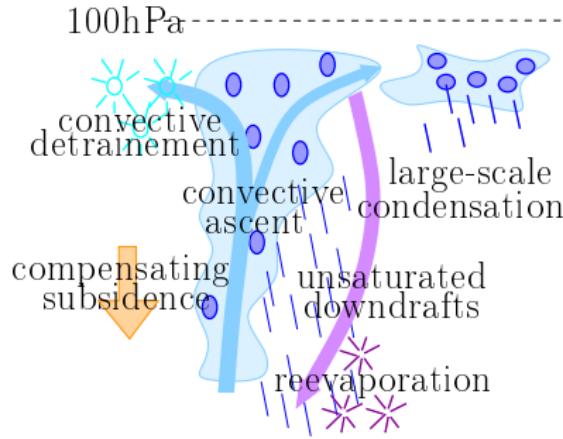

- ▶ Moistening and dehydrating processes (*Worden et al 2007*)

- |   |  |
|---|--|
| <p>→ large-scale condensation</p> <p>→ subsidence</p> | <p>→ detrainment</p> <p>→ rain reevaporation</p> |
|---|--|

# Theoretical framework: $q\text{-}\delta D$

- Moistening and dehydrating processes (*Worden et al 2007*)

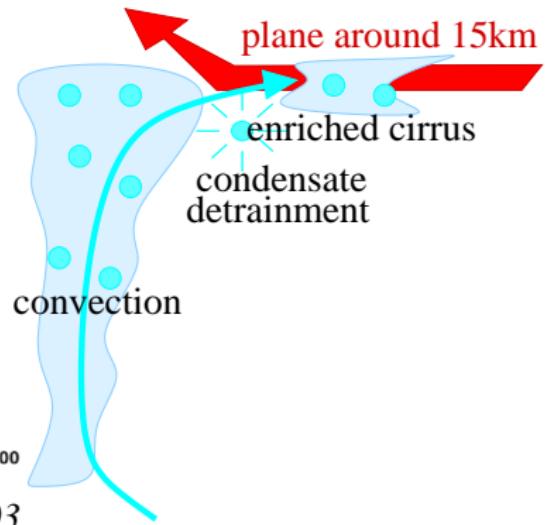

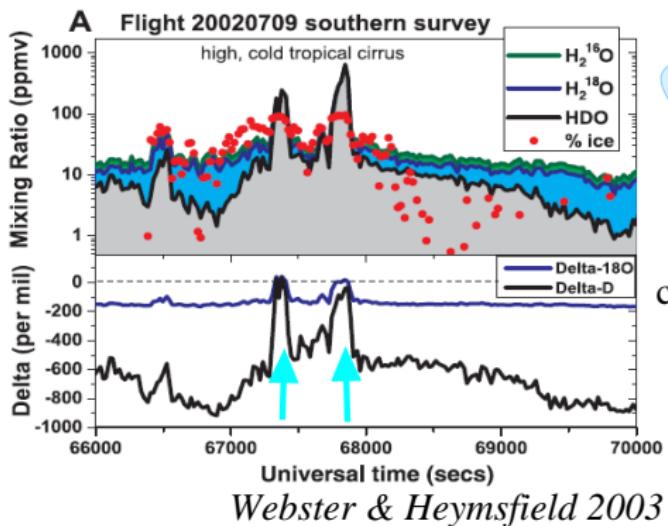

→ large-scale condensation → subsidence	→ detrainment → rain reevaporation
--	---------------------------------------

- limitation: need to bridge gap between this simple framework and numerical modeling

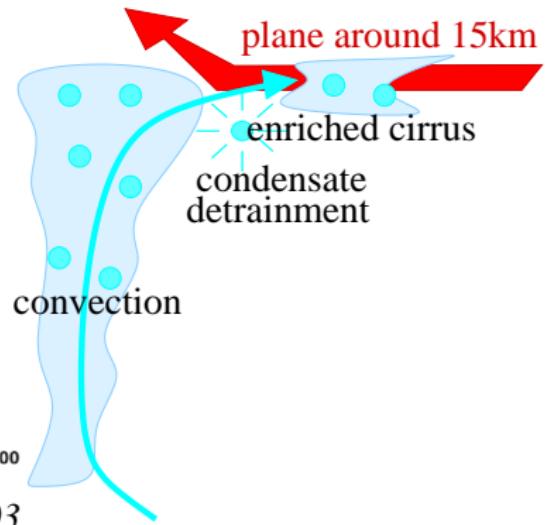

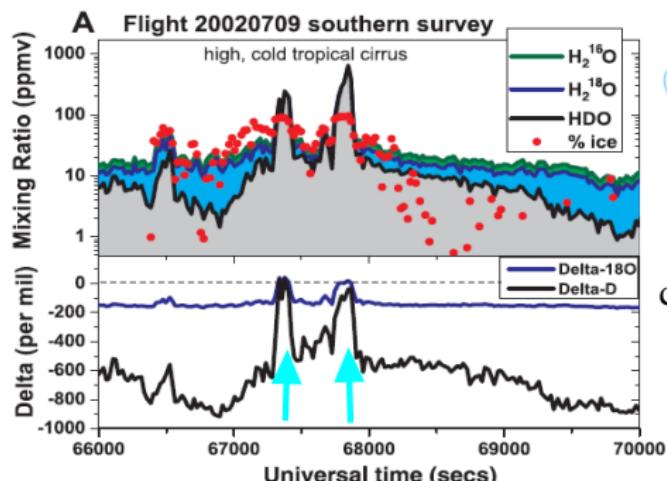

# Isotopes in the upper troposphere

- ▶ papers from *Moyer, Kuang, Dessler, Sherwood, Sayres, Hanicco...*

# Isotopes in the upper troposphere

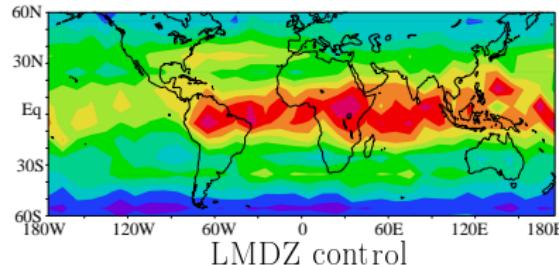

- ▶ papers from *Moyer, Kuang, Dessler, Sherwood, Sayres, Hanicco...*

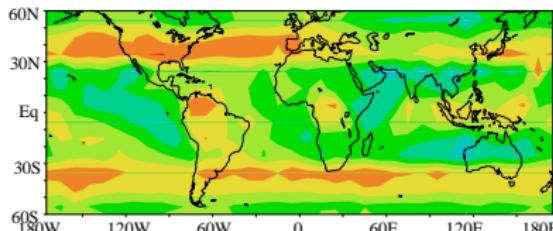

- ▶ Limitation: isotopes consistent with some convective injection of water through the tropopause layer. But how to make quantitative estimations?

# Convective detrainment in upper troposphere

MIPAS data at 200hPa, annual

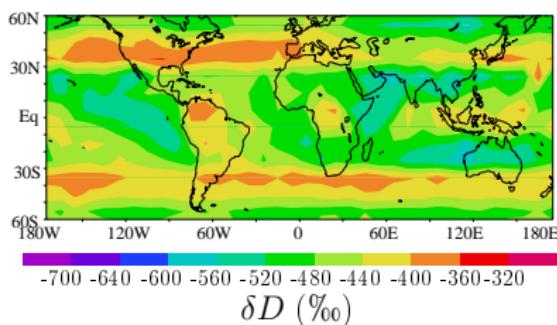

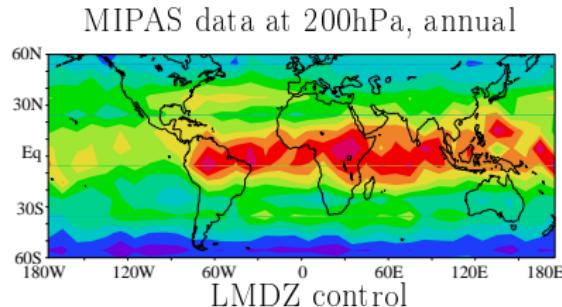

LMDZ control

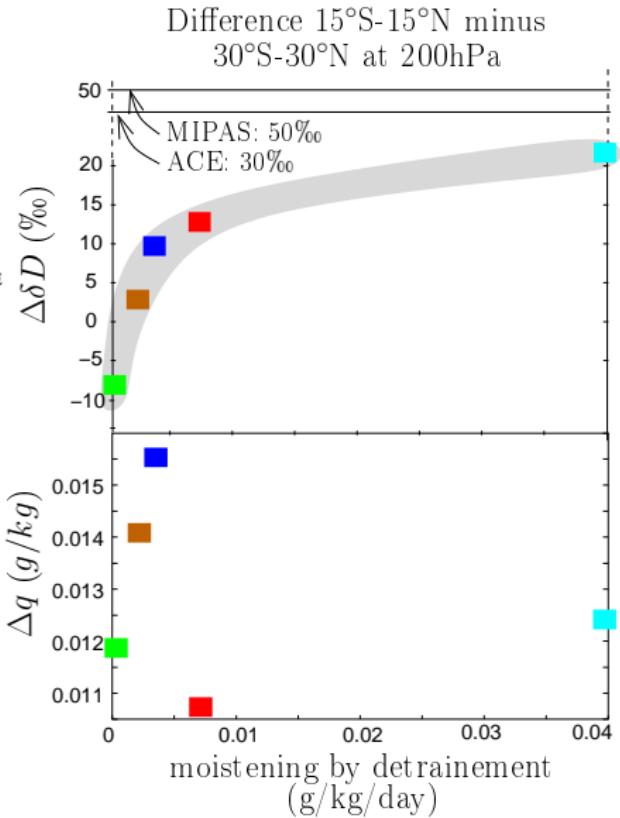

-700 -640 -600 -560 -520 -480 -440 -400 -360 -320  
 $\delta D$  (%)

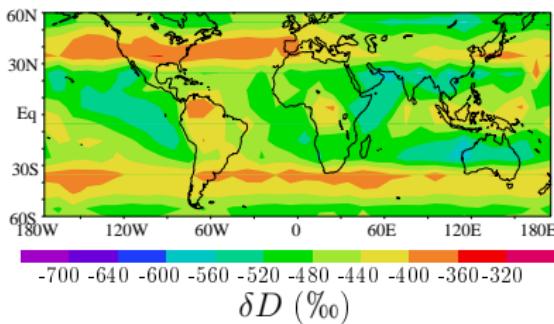

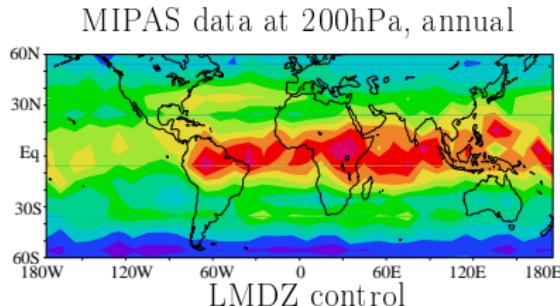

# Convective detrainment in upper troposphere

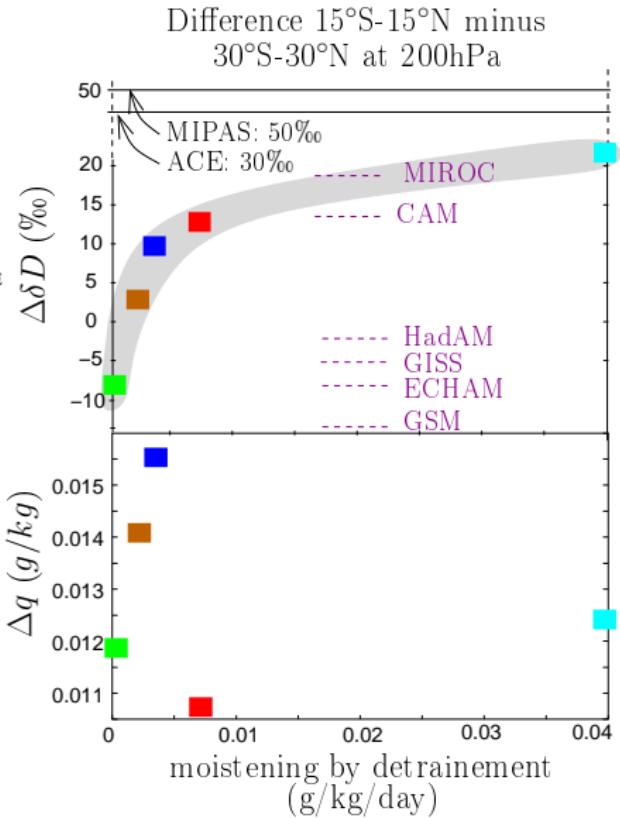

- control
- vertical advection more diffusive
- stronger condensate detrainment
- less large-scale condensation
- less large-scale precipitation

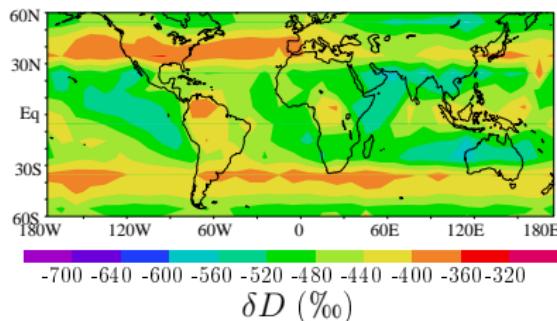

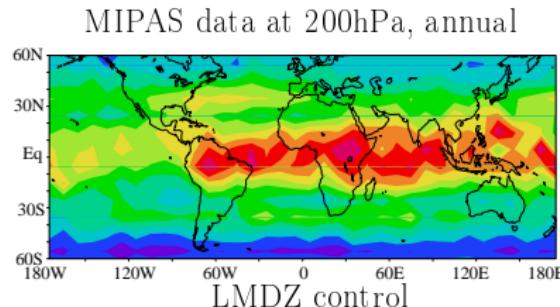

# Convective detrainment in upper troposphere

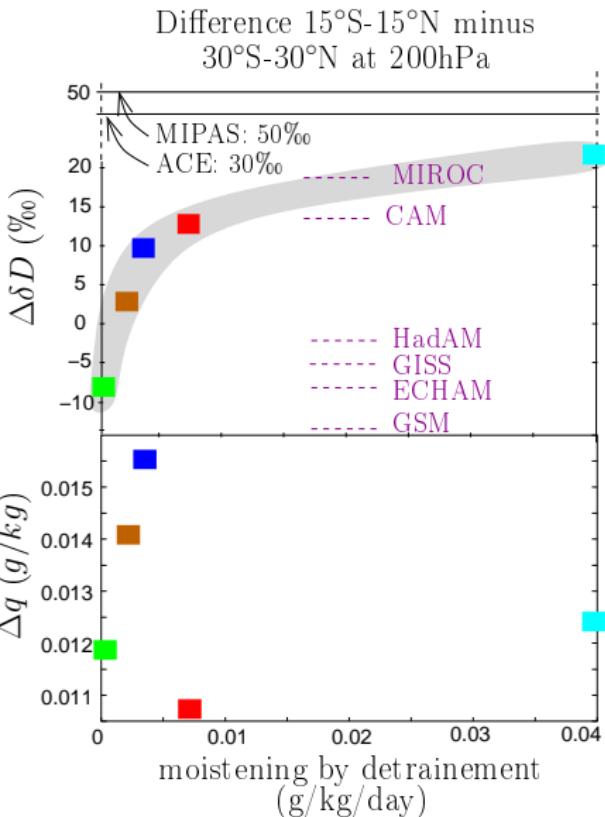

- control
- vertical advection more diffusive
- stronger condensate detrainment
- less large-scale condensation
- less large-scale precipitation

# Convective detrainment in upper troposphere

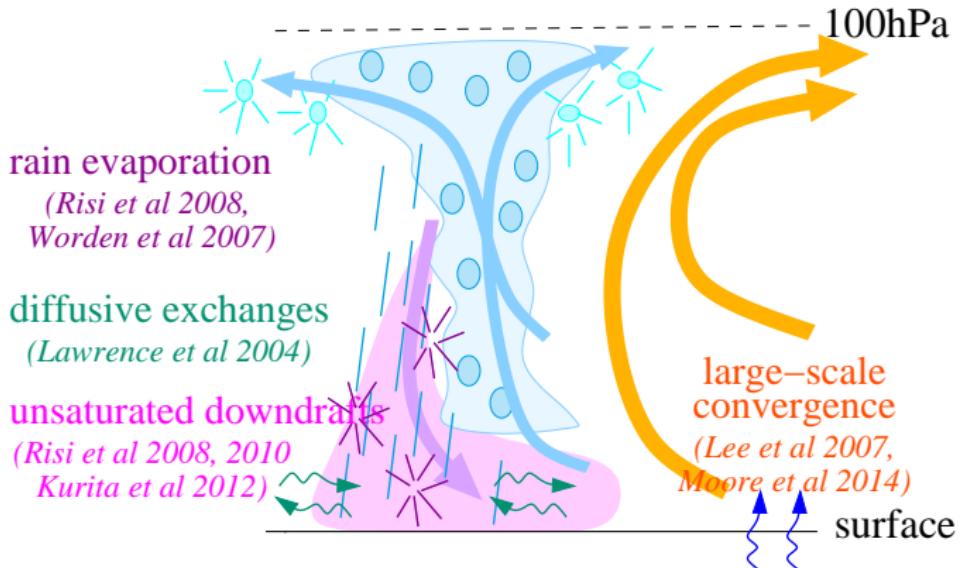

- control
- vertical advection more diffusive
- stronger condensate detrainment
- less large-scale condensation
- less large-scale precipitation

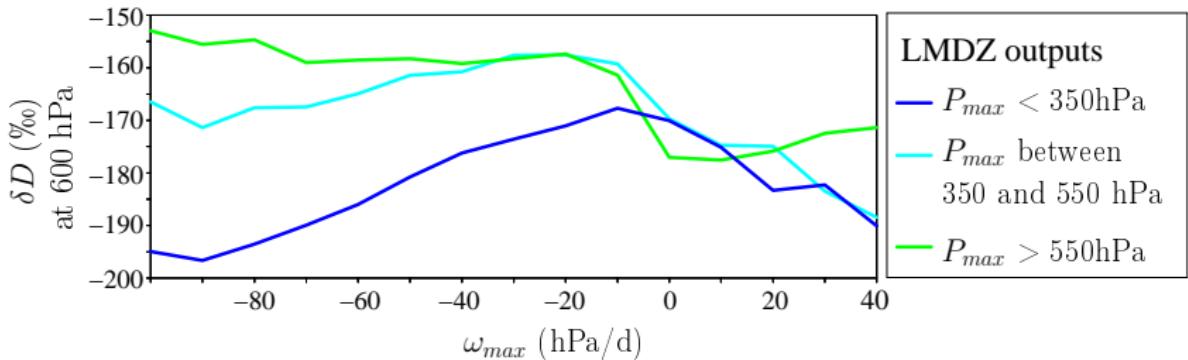

# Lower and mid troposphere

- ▶ “amount effect”:  $\delta D \searrow$  as precipitation  $\searrow$

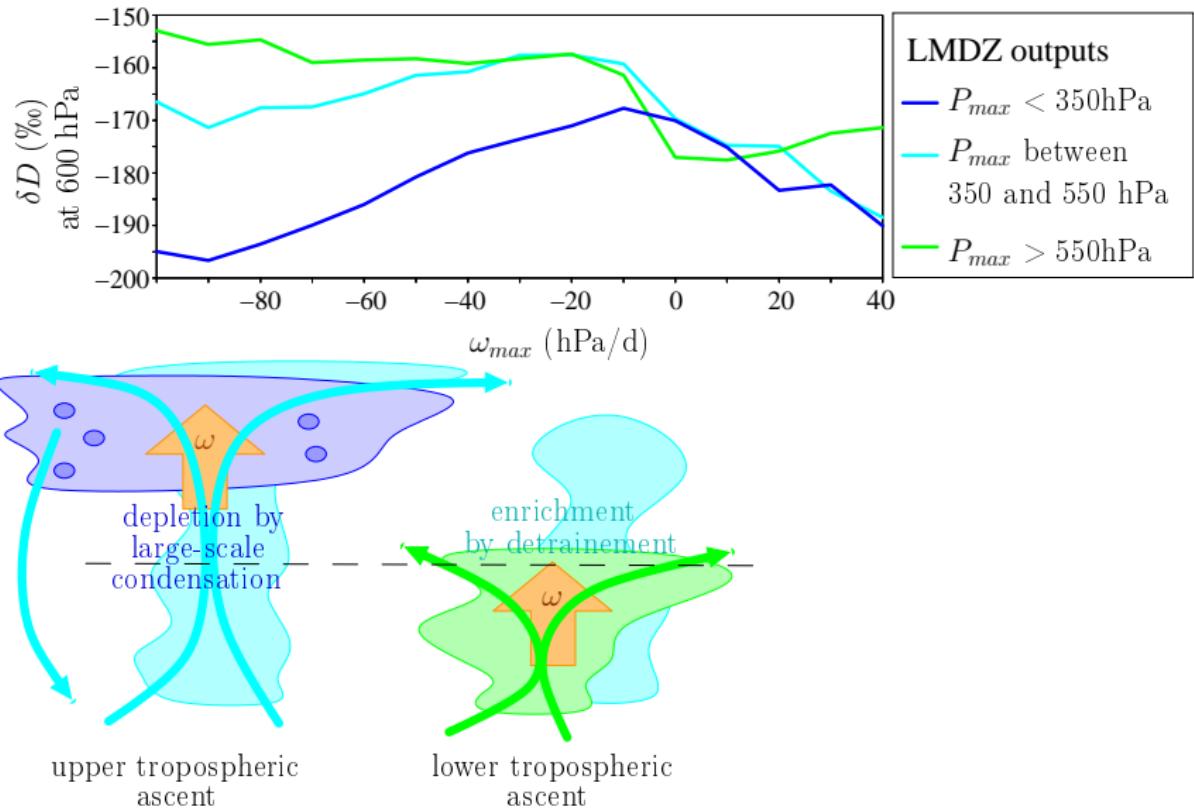

- ▶ What does amount effect amplitude says about model physics?

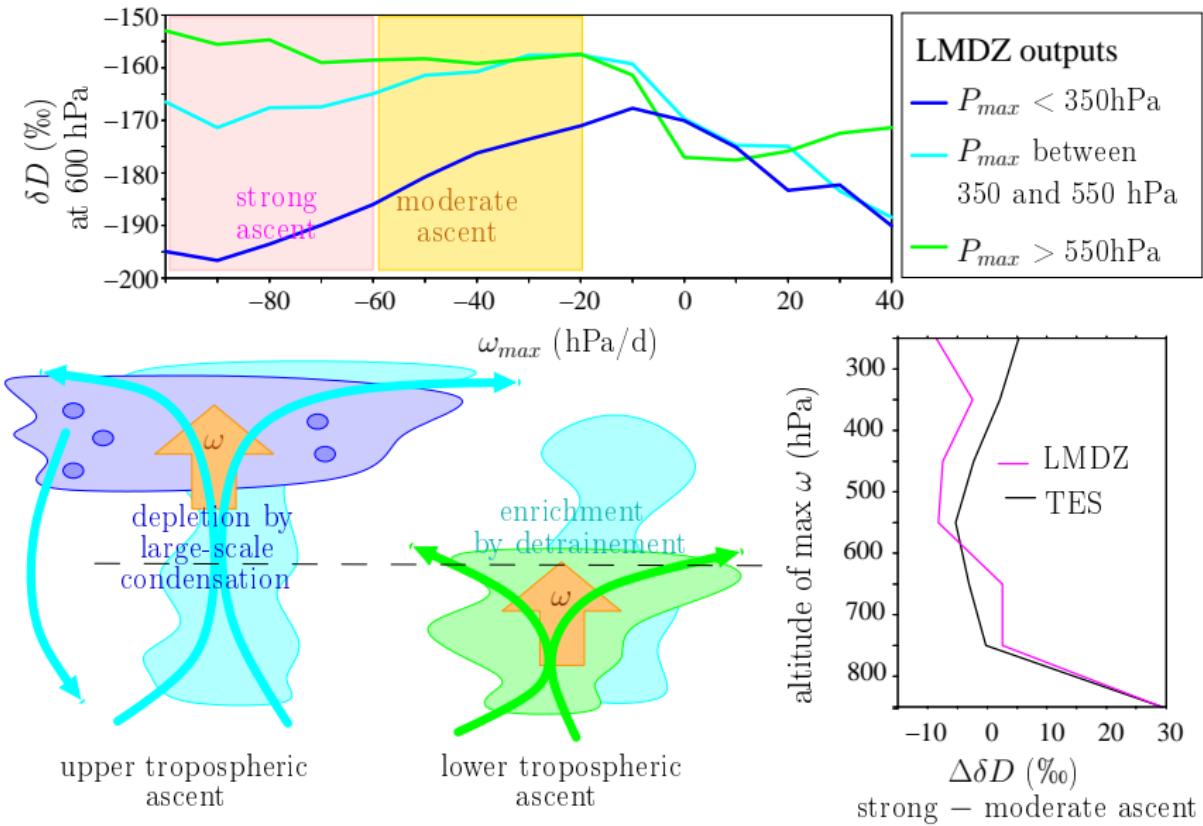

# Sensitivity to large-scale velocity profile

# Sensitivity to large-scale velocity profile

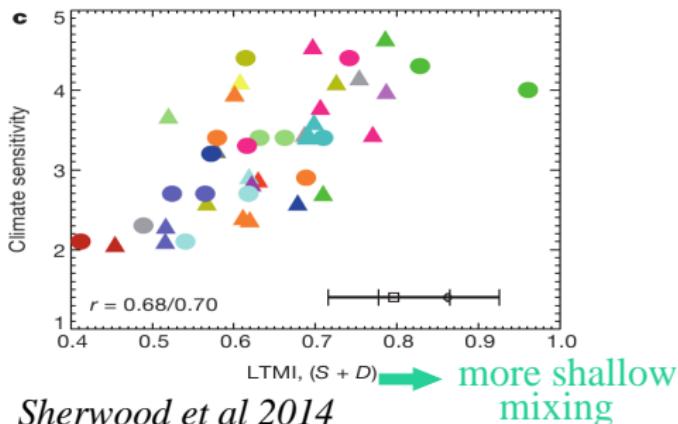

# Sensitivity to large-scale velocity profile

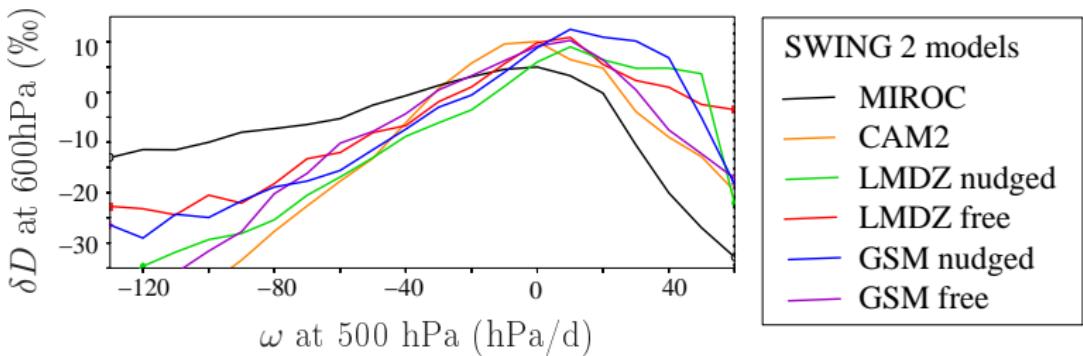

# Implications

- ▶ Precipitation depletes the tropospheric vapor all the more as it is associated with top-heavy ascent
- ▶ amount effect amplitude reflects top-heaviness of circulation and associated latent heat profiles, i.e. conv vs shallow
- ▶ Key factor for cloud feedbacks? (*Sherwood et al 2014*)

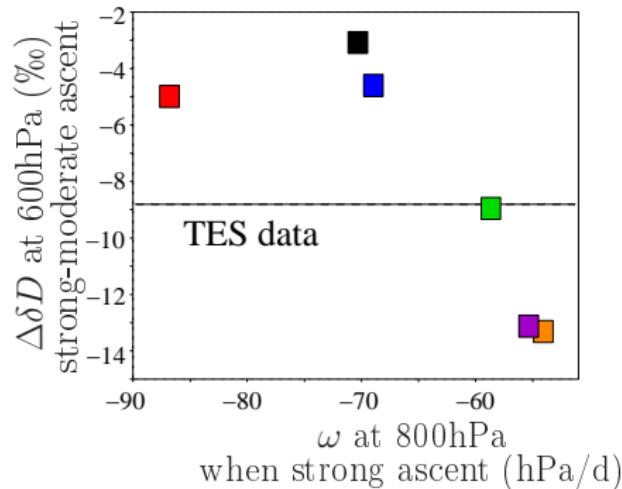

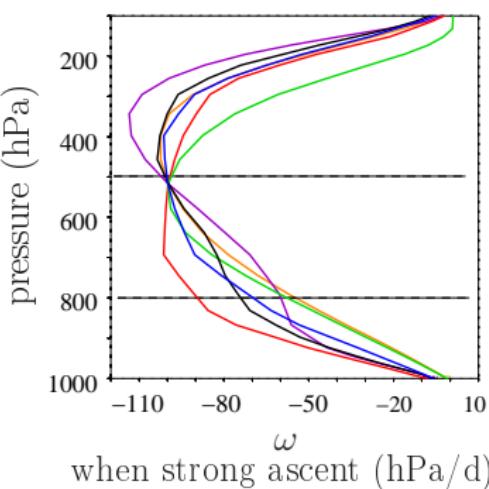

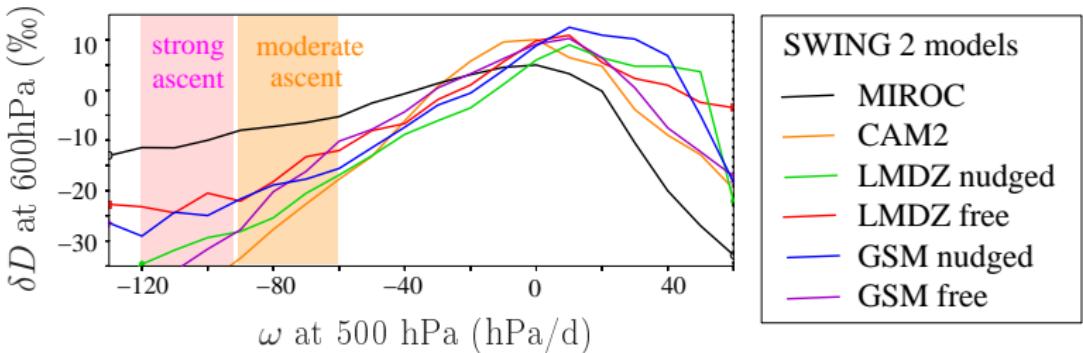

⇒ use it evaluate deep vs shallow convective mixing and associated large-scale circulation?

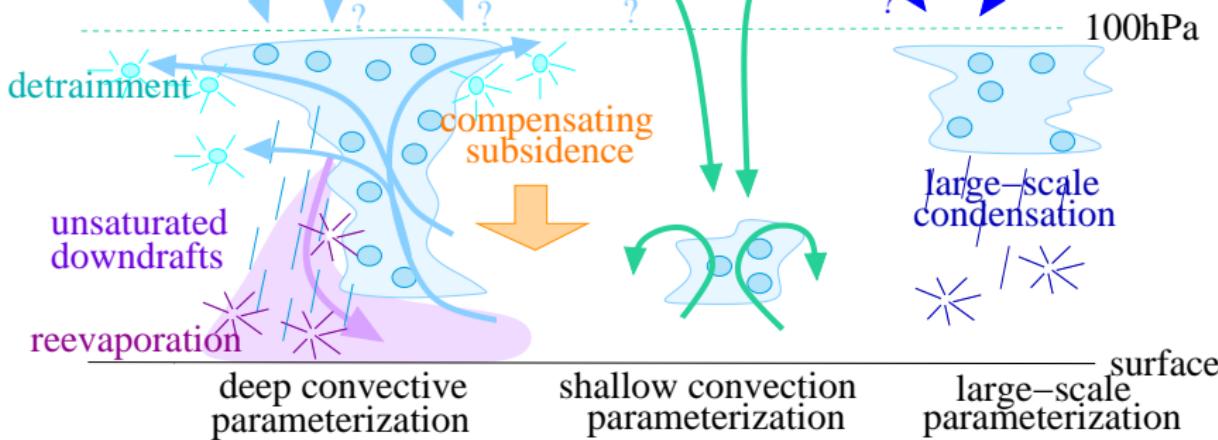

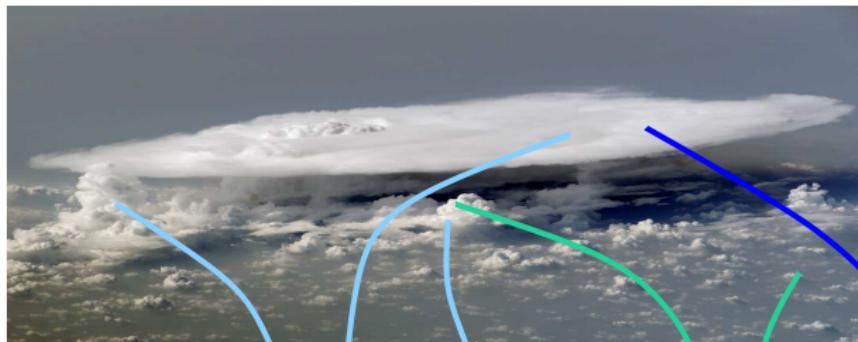

## And across models?

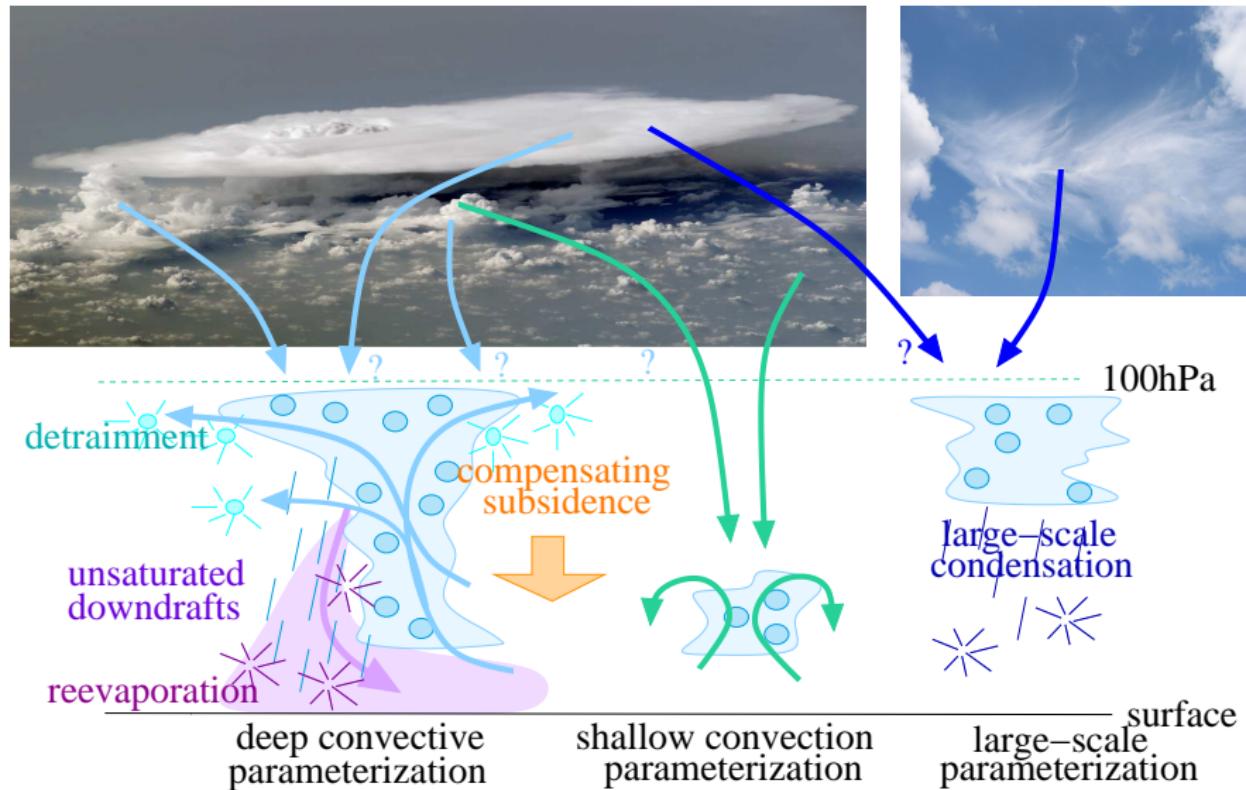

# And across models?

### 3) Convection vs large-scale schemes

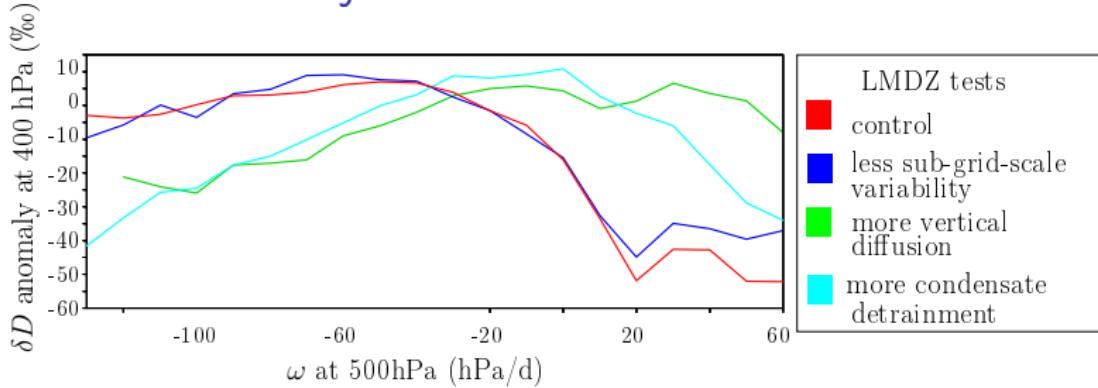

### 3) Convection vs large-scale schemes

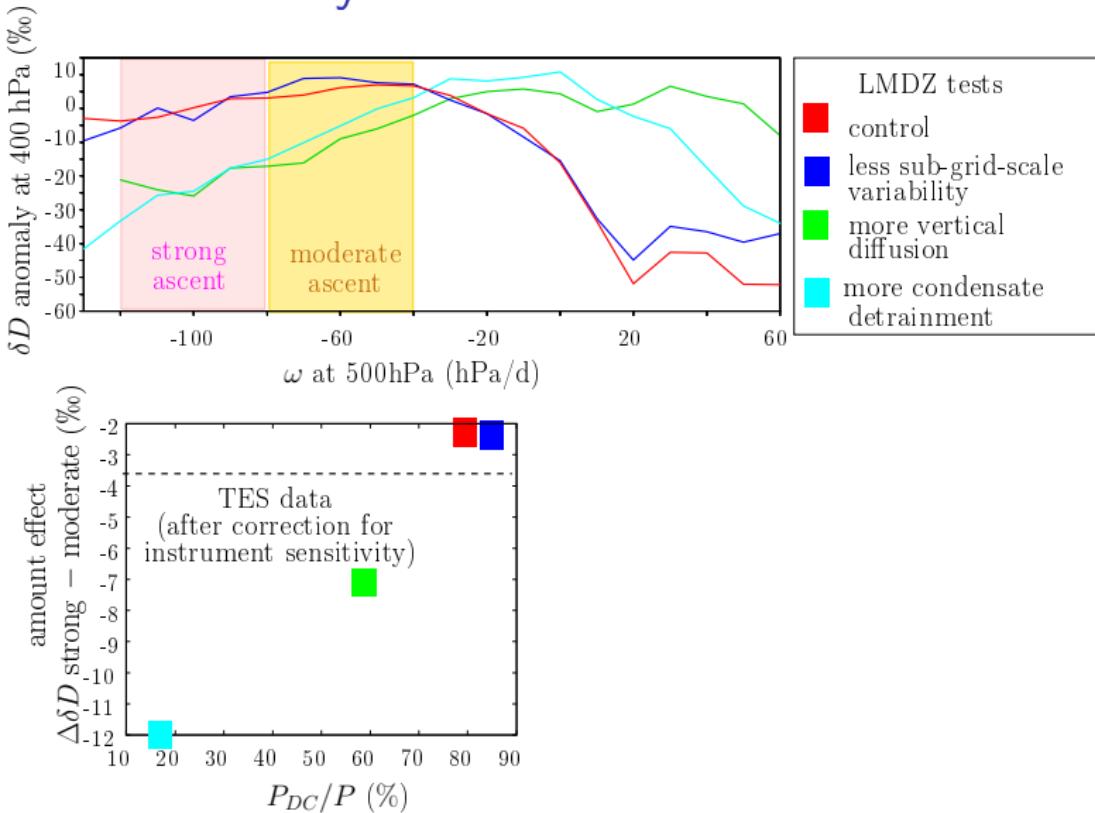

► conv vs large-scale precip arbitrary

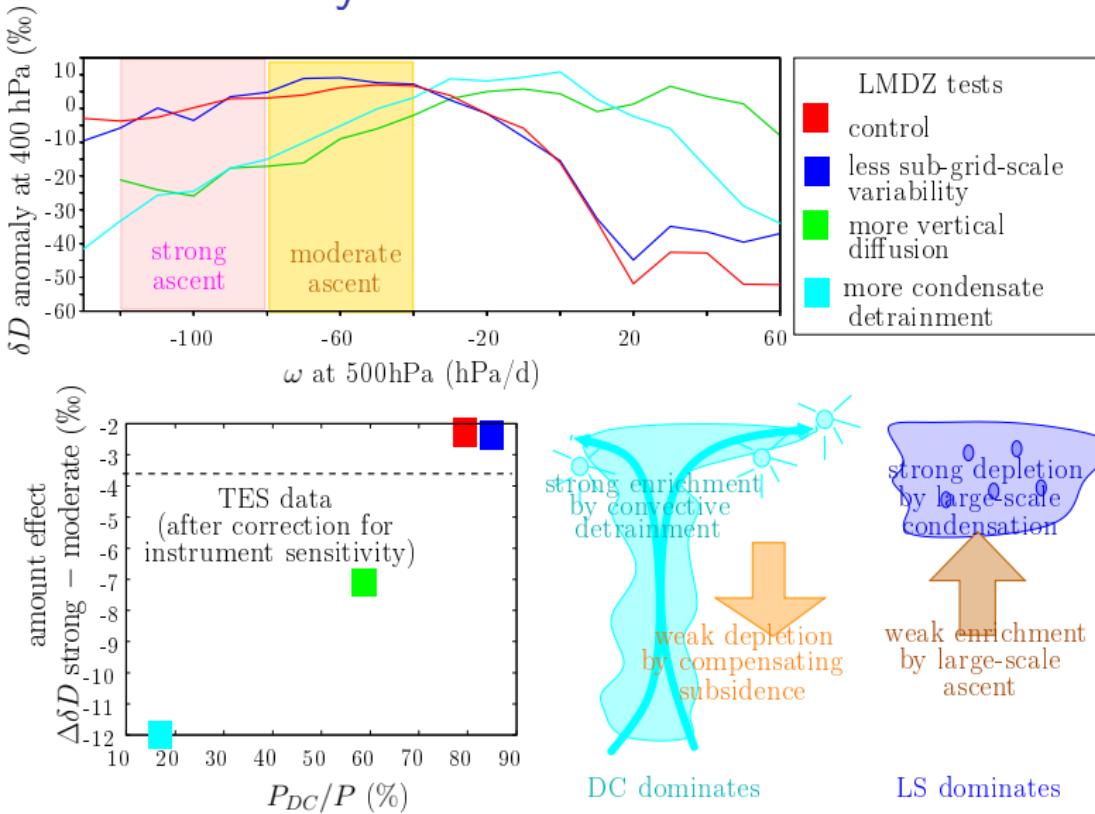

## Sensitivity tests in LMDZ

# Sensitivity tests in LMDZ

## Sensitivity tests in LMDZ

# Implications

- ▶ precipitating events deplete the tropospheric vapor all the more as it is associated with large-scale precipitation
- ▶ conv vs large-scale precipitation = arbitrary choice specific to each model, but with consequences on:
  - ▶ latent heating profiles  $\Rightarrow$  large-scale circulation
  - ▶ cloudiness
  - ▶ water vapor, chemical and aerosol transport
  - ▶ intra-seasonal variability (*Kim et al 2012*)

$\Rightarrow$  use water isotopes quantitatively to evaluate conv vs large-scale precip partitioning and underlying heating profiles?

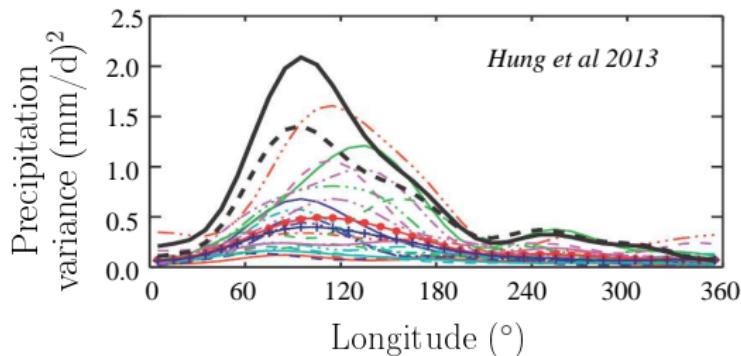

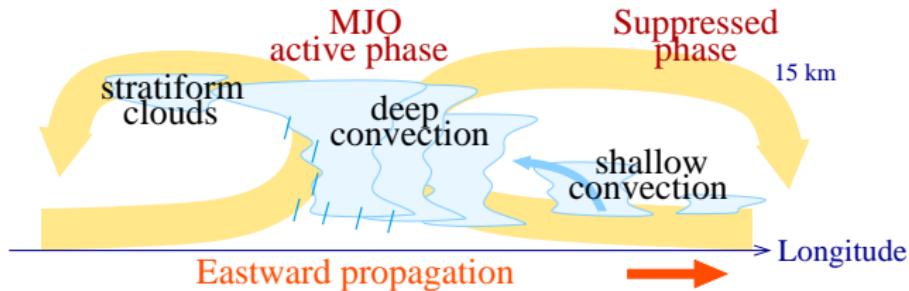

# Implications

- ▶ precipitating events deplete the tropospheric vapor all the more as it is associated with large-scale precipitation
- ▶ conv vs large-scale precipitation = arbitrary choice specific to each model, but with consequences on:
  - ▶ latent heating profiles ⇒ large-scale circulation
  - ▶ cloudiness
  - ▶ water vapor, chemical and aerosol transport
  - ▶ intra-seasonal variability (*Kim et al 2012*)

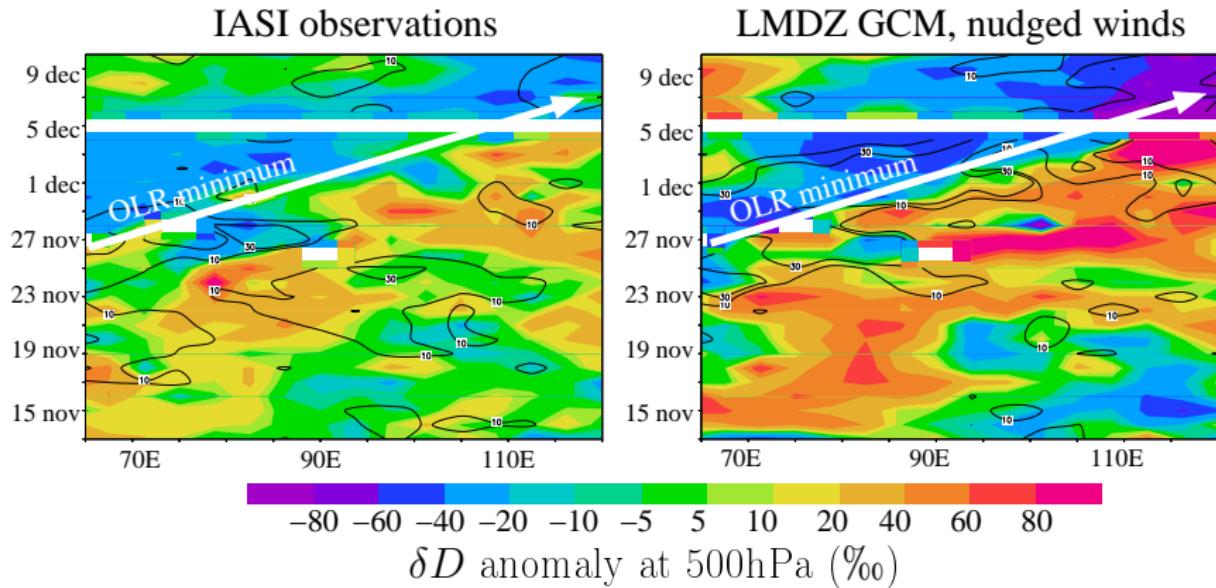

⇒ use water isotopes quantitatively to evaluate conv vs large-scale precip partitioning and underlying heating profiles?

- ▶ work in progress with SCM
- ▶ Obbe Tuinenbourg's work: use water isotopes to evaluate sequence of cloud processes during the Madden-Julian Oscillation (MJO)?

## 4) MJO so difficult to simulate?

# Cindy Dynamo campaign case

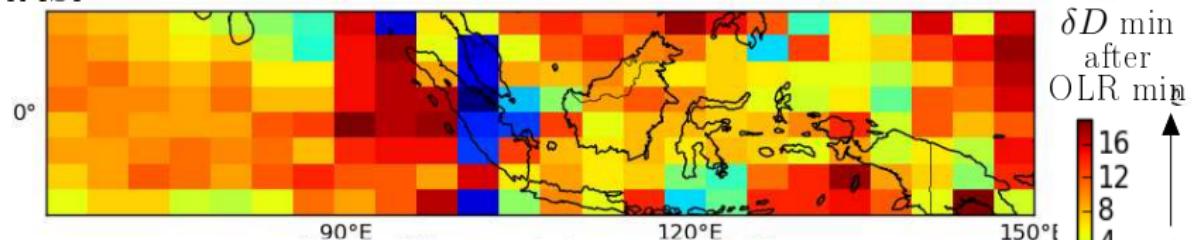

- ▶ Observed  $q$  max 0-1 days before OLR min
- ▶ Observed  $\delta D$  min 3 days after OLR min
- ▶ LMDZ captures this lag for this case

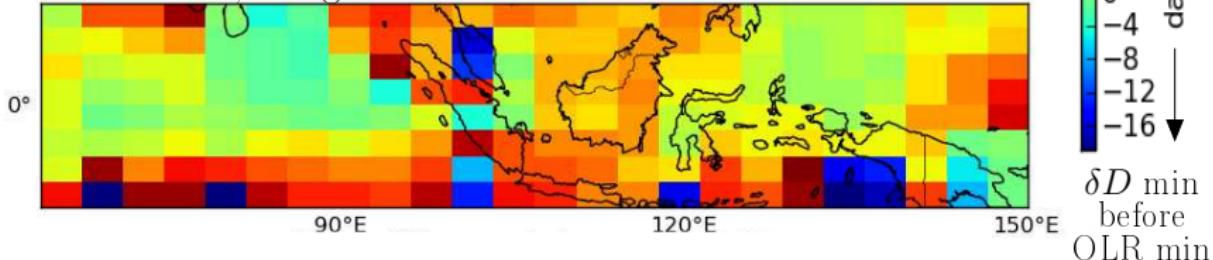

# Statistical analysis for 2006-2007

Phasing of  $\delta D$  min at 500hPa vs OLR min

IASI

LMDZ GCM, nudged winds

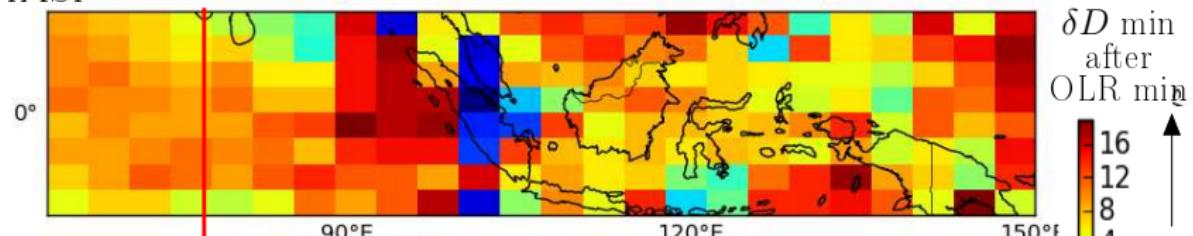

- ▶ Observed  $\delta D$  min lags OLR min in Indian Ocean
- ▶ More complicated over Maritime Continent
- ▶ LMDZ  $\delta D$  to in phase with OLR

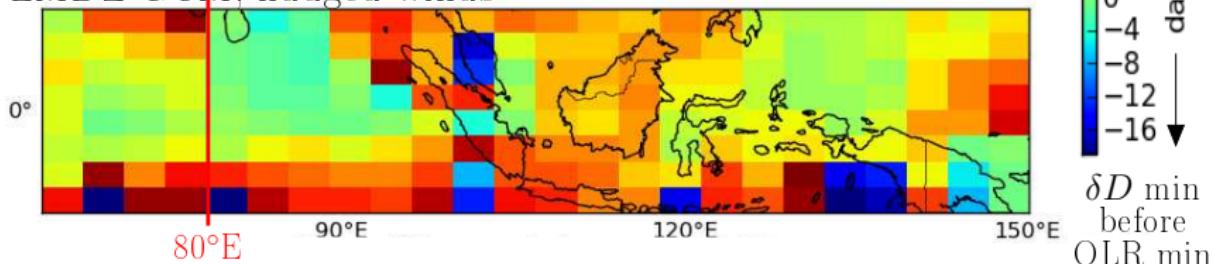

# Statistical analysis for 2006-2007

Phasing of  $\delta D$  min at 500hPa vs OLR min

IASI

LMDZ GCM, nudged winds

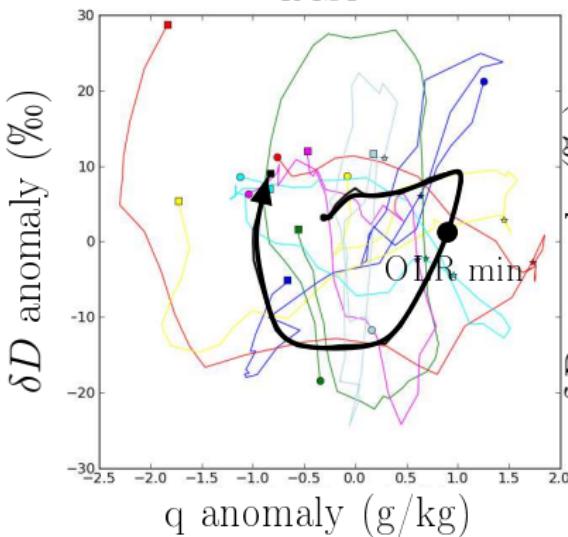

- ▶ Observed  $\delta D$  min lags OLR min in Indian Ocean
- ▶ More complicated over Maritime Continent
- 4) MJO ▶ LMDZ  $\delta D$  to in phase with OLR

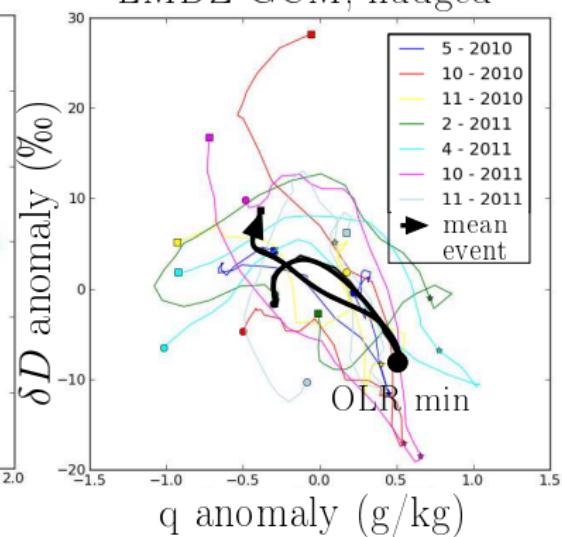

# $q$ - $\delta D$ cycles in Indian Ocean

$q$ - $\delta D$  cycles at 500 hPa for 7 MJO events at  $80^{\circ}\text{E}$

IASI

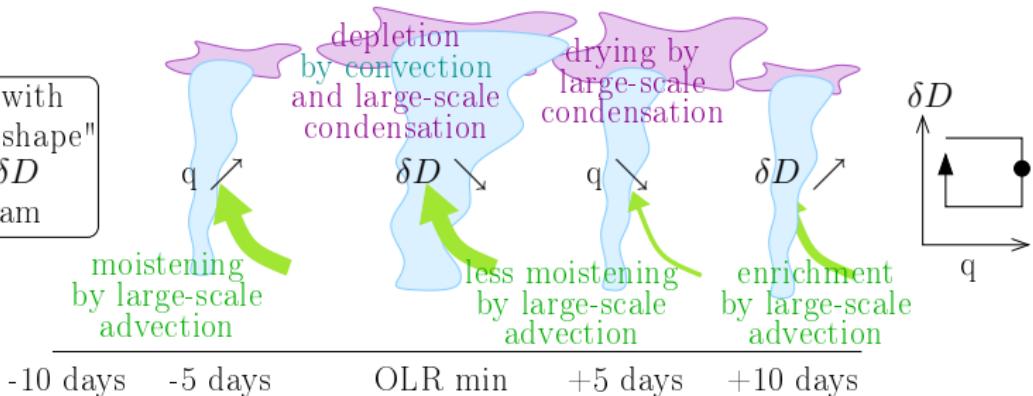

LMDZ GCM, nudged

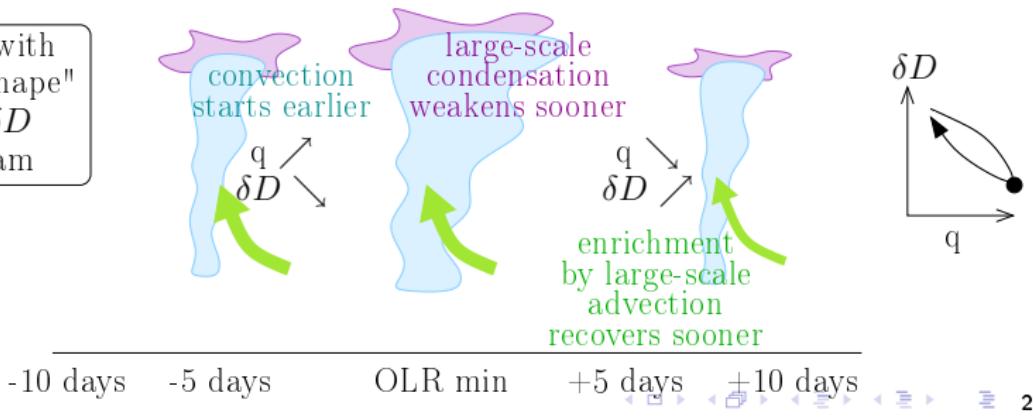

- ▶ Observations: “circular”, clockwise shape
- ▶ LMDZ: sometimes circular, too often “linear”: why?

# What determines $q - \delta D$ shape in LMDZ?

events with  
"circular shape"  
in  $q - \delta D$   
diagram

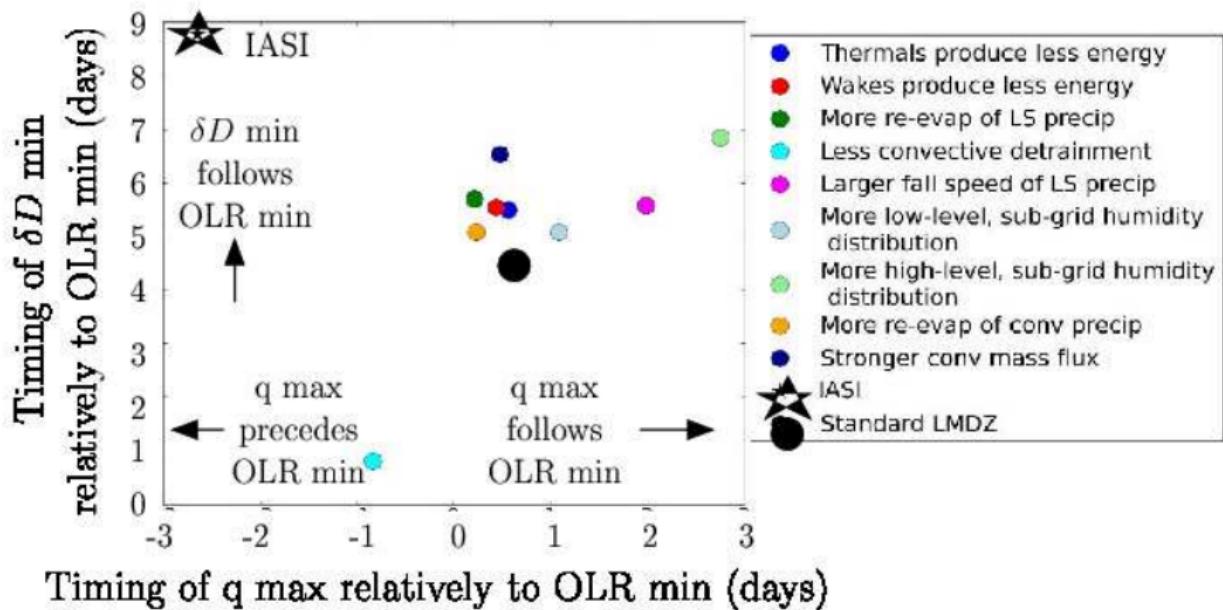

events with  
"linear shape"  
in  $q - \delta D$   
diagram

# Preliminary summary on $q - \delta D$ cycles during the MJO

- ▶ Observed “circular shape” over Indian Ocean consistent with cloud evolution shallow → deep → stratiform
- ▶ What happens over the Maritime Continent?
- ▶ Still lot of work to fully understand both data and model behavior
- ▶ LMDZ too in phase:
  - ▶ convection triggers too soon?
  - ▶ Large-scale condensation not maintained long enough?
  - ▶ Large-scale advective enrichment recovers too soon?
- ▶  $q - \delta D$  useful for model evaluation?  $\Rightarrow$  work in progress: analyze sensitivity tests

# Sensitivity tests with LMDZ

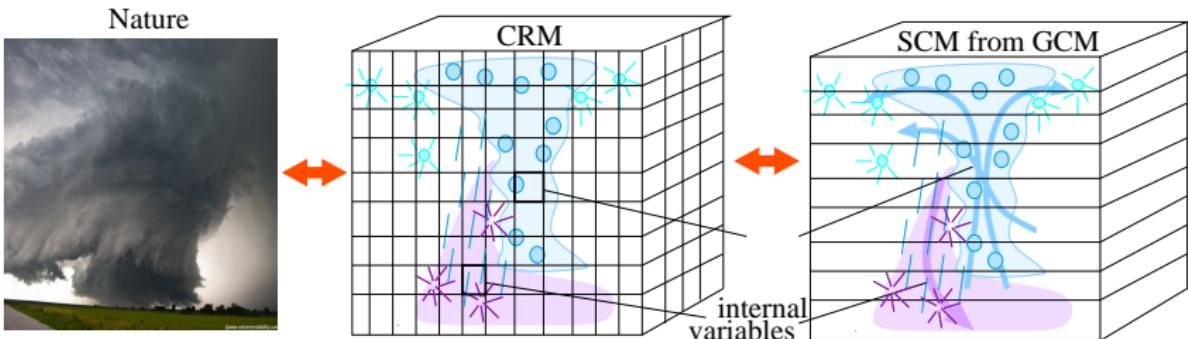

- ▶  $q - \delta D$  shape sensitive to convection/cloud parameters
- ▶ How to get closer to observations?

## Summary on $q - \delta D$ cycles during the MJO

- ▶  $q - \delta D$  cycles during MJO: informs about the relative timing of shallow convection, deep convection, large-scale condensation and large-scale advection
- ▶ Potentially useful for model evaluation
- ▶ Still lot of work to fully understand both data and model behavior
- ▶ Exploit better the Cindy Dynamo campaign data?

## General perspectives

- ▶ Bridge gap between simple theoretical  $q - \delta D$  framework and more complex modeling
  - ▶ Better exploit model hierarchy: GCM vs SCM, with large-scale circulation as forcing or as a response (WTG).
  - ▶ intercompare GCMs: add daily in SWING2?
  - ▶ CRM/LES to study processes and to compare more easily to observations and to SCMs (conditional sampling)

- ▶ longer term: combine  $q$ ,  $\delta D$  + chemical tracers: CO,  $O_3$ ,  $^{10}Be$   
 $\Rightarrow$  better characterize fluxes
